## ABSTRACT

### 1. INTRODUCTION

### 2. EQUATIONS OF MOTION

The equations of motion for a two dimensional, viscous disk are

$$(\partial_t + \mathbf{v} \cdot \nabla) \mathbf{v} = -\frac{\nabla P}{\Sigma} - \nabla \Phi + \frac{1}{\Sigma} \nabla \cdot (\nu \Sigma \mathbf{D}) \quad (1)$$

$$(\partial_t + \mathbf{v} \cdot \nabla) \Sigma = -\Sigma \nabla \cdot \mathbf{v} \quad (2)$$

$$T(\partial_t + \mathbf{v} \cdot \nabla) s = -\frac{T - \bar{T}}{t_{\text{cool}}} \quad (3)$$

Where all quantities are assumed to be a vertical average of their three dimensional counterparts. Here,  $\Sigma$  is the surface density,  $s$  is the entropy of the fluid,  $T$  is the disk temperature, and  $\mathbf{D}$  is the viscous stress tensor. These equations describe a viscous fluid that is thermally heated and or cooled to some "background" temperature profile  $\bar{T}$  over a timescale  $t_{\text{cool}}$ . To close the system of equations we assume the fluid is ideal and perfect, so that  $P = \mathcal{R} \Sigma T$  and  $s \equiv \frac{\mathcal{R}}{\gamma-1} \ln(P \Sigma^{-\gamma})$ ; hereafter we set  $\mathcal{R} = 1$  without loss of generality. Following ?, we can connect the two dimension adiabatic index  $\gamma$  to the true three dimensional adiabatic index  $\Gamma$  by assuming that the gas is vertically isothermal and gaussian distributed.

We consider a disk with a prescribed azimuthally averaged background profile given by  $(\bar{v}_r, \bar{v}_\phi, \bar{\Sigma}, \bar{T}) = (0, r\Omega(r), \bar{\Sigma} \propto r^\mu, \bar{T} \propto r^\delta)$ . We look at linear perturbations to this background state. Denoted linear quantities with a prime and background quantities with a bar, the linearized equations of motion become

$$(\partial_t + \Omega \partial_\phi) v'_r - 2\Omega v'_\phi = -\frac{1}{\Sigma} \partial_r P' + \frac{\Sigma'}{\bar{\Sigma}^2} \frac{d\bar{P}}{dr} - \partial_r \Phi' + \text{visc.} \quad (4)$$

$$(\partial_t + \Omega \partial_\phi) v'_\phi + \frac{\kappa^2}{2\Omega} v'_r = -\frac{1}{r\bar{\Sigma}} \partial_\phi P' - \frac{1}{r} \partial_\phi \Phi' + \text{visc.} \quad (5)$$

$$(\partial_t + \Omega \partial_\phi) \Sigma' + v'_r \frac{d\bar{\Sigma}}{dr} = -\bar{\Sigma} \left( \frac{1}{r} \partial_r (r v'_r) + \frac{1}{r} \partial_\phi (v'_\phi) \right) \quad (6)$$

$$(\partial_t + \Omega \partial_\phi) s' + v'_r \frac{d\bar{s}}{dr} = -\beta \Omega \frac{T'}{\bar{T}} \quad (7)$$

Where we've parametrized the cooling time as  $t_{\text{cool}}^{-1} = \beta \Omega$  (?). We now Fourier Transform the linear variables in the azimuthal direction as well as in time and write  $(v'_r, v'_\phi, \Sigma', P', s', T', \Phi') = \sum_m (u, v, \sigma, p, s, T, \phi) e^{im(\phi - \Omega_p t)}$ . We further work under

the assumption that the different  $m$  modes only couple to the  $m = 0$  mode (i.e the background) and not to other  $m \neq 0$  modes. The linearized equations of motion are now

$$im(\Omega - \Omega_p)u - 2\Omega v = -\frac{1}{\bar{\Sigma}} \frac{dp}{dr} + \frac{\sigma}{\bar{\Sigma}^2} \frac{d\bar{P}}{dr} - \frac{d\phi}{dr} + \text{visc.} \quad (8)$$

$$im(\Omega - \Omega_p)v + \frac{\kappa^2}{2\Omega} u = -\frac{imp}{r\bar{\Sigma}} - \frac{im\phi}{r} + \text{visc.} \quad (9)$$

$$im(\Omega - \Omega_p) \frac{\sigma}{\bar{\Sigma}} + u \frac{d \ln \bar{\Sigma}}{dr} = -\left( \frac{1}{r} \frac{d}{dr} (ru) + \frac{imv}{r} \right) \quad (10)$$

$$im \left[ \left( 1 - i \frac{\beta(\gamma-1)}{m} \right) \Omega - \Omega_p \right] \frac{T'}{\bar{T}} + u \frac{d \ln \bar{T}}{dr} = -(\gamma-1) \left( \frac{1}{r} \frac{d}{dr} (ru) + \frac{imv}{r} \right) \quad (11)$$

Where we've replaced the entropy in favor of the temperature through the relations

$$(\gamma-1)s' = \frac{T'}{\bar{T}} - (\gamma-1) \frac{\sigma}{\bar{\Sigma}} \quad (12)$$

$$(\gamma-1) \frac{d\bar{s}}{dr} = \frac{d \ln \bar{T}}{dr} - (\gamma-1) \frac{d \ln \bar{\Sigma}}{dr} \quad (13)$$

### 3. $m = 1$ SLOW MODES

We specialize to  $m = 1$  modes and to the low pattern speed limit  $\Omega_p \ll \Omega$ . We can simplify the 4 dimensional set of equations to just one equation describing the global structure and evolution of an eccentricity vector,  $e(r)$  (???). The eccentricity is defined through the Lagrangian displacement  $\xi_r$  as

$$e \equiv \frac{\xi_r}{r} \quad (14)$$

Following ? we can write an evolution equation for the disk eccentricity by an appropriate linear combination of the two momenta equations and using

$$2\Omega r^3 (\Omega_p - \omega_p) e = -\frac{d}{dr} \left( r^2 \frac{p}{\bar{\Sigma}} + r^2 \phi \right) + \frac{r^2}{\bar{\Sigma}^2} \left[ \sigma \frac{d\bar{P}}{dr} - p \frac{d\bar{\Sigma}}{dr} \right] \quad (15)$$

$$2\Omega r^3 \omega_p = -r \frac{d}{dr} \left( \frac{r^2}{\bar{\Sigma}} \frac{d\bar{P}}{dr} \right) - r \frac{d}{dr} \left( r^2 \frac{d\bar{\Phi}}{dr} \right) \quad (16)$$

$$p = \sigma \bar{T} + \bar{\Sigma} T' \quad (17)$$

$$\frac{\sigma}{\bar{\Sigma}} = -\frac{d \ln \bar{\Sigma}}{d \ln r} e - r \frac{de}{dr} \quad (18)$$

$$(1 - i\tilde{\beta})\frac{T'}{\bar{T}} = -\frac{d \ln \bar{T}}{d \ln r}e - (\gamma - 1)r\frac{de}{dr} \quad (19)$$

$$(1 - i\tilde{\beta})\frac{p}{\bar{P}} = -\left[\left(\frac{d \ln \bar{T}}{d \ln r} + (1 - i\tilde{\beta})\frac{d \ln \bar{\Sigma}}{d \ln r}\right)e + (\gamma - i\tilde{\beta})r\frac{de}{dr}\right] \quad (20)$$

### 3.1. No Cooling

We define the adiabatic limit as when  $\beta = 0$ , the eccentricity equation in this limit reduces to,

$$2\Omega r^3(\Omega_p - \omega_p)e = -\frac{d}{dr}\left(\frac{r^2 p}{\bar{\Sigma}} + r^2 \phi\right) + \frac{r^2}{\bar{\Sigma}}\left(\sigma \frac{d\bar{P}}{dr} - p \frac{d\bar{\Sigma}}{dr}\right) \quad (21)$$

$$\frac{p}{\bar{P}} = -\frac{d \ln \bar{P}}{d \ln r}e - \gamma r \frac{de}{dr} \quad (22)$$

This is equivalent to the eccentricity equation of e.g. ? (their Eq. 21), when we use (??) to replace  $\omega_p$ .

We define the barotropic limit as when  $\gamma \rightarrow 1$  and we can write the total pressure as  $P = P(\Sigma)$ . We then define the sound speed  $c^2$ , such that,  $p = c^2 \sigma$  and  $\frac{d\bar{P}}{d\bar{\Sigma}} = c^2$ . The eccentricity equation simplifies in this case to,

$$2\Omega r^3(\Omega_p - \omega_p)e = -\frac{d}{dr}\left(r^2 \frac{c^2 \sigma}{\bar{\Sigma}} + r^2 \phi\right) \quad (23)$$

This is equivalent to the eccentricity equation of e.g. ? (his Eq. 18).

The locally isothermal limit is defined as  $\gamma \rightarrow 1$  and  $P = \bar{T}(r)\bar{\Sigma}$ . The eccentricity equation in the locally isothermal limit is then,

$$2\Omega r^3(\Omega_p - \omega_p)e = -\bar{T}\frac{d}{dr}\left(r^2 \frac{\sigma}{\bar{\Sigma}}\right) - \frac{d}{dr}(r^2 \phi) \quad (24)$$

This is equivalent to the linear system that e.g. ? studied.

### 3.2. With Cooling

Which follow from (??) & (??) to zeroth order in  $\Omega_p$  and with  $\Omega \approx \Omega_K$ . We obtain the evolution equation

$$\Omega_p e = A e + B \frac{de}{d \ln r} + C \frac{d^2 e}{d \ln r^2} \quad (25)$$

Where the coefficients are,

$$A = \omega_p + \mathcal{H}\left[2\mu + \mu' + \frac{1}{1 - i\tilde{\beta}}(\delta' + \delta(2 + \mu + \delta))\right] \quad (26)$$

$$B = \mathcal{H}\left[2 + \mu + \frac{1}{1 - i\tilde{\beta}}((\gamma\delta + (\gamma - 1)(2 + \mu))\right] \quad (27)$$

$$C = \mathcal{H}\left[1 + \frac{(\gamma - 1)}{1 - i\tilde{\beta}}\right] \quad (28)$$

Where,

$$\tilde{\beta} \equiv \beta(\gamma - 1) \quad (29)$$

$$\mathcal{H} \equiv \frac{\bar{T}}{2\Omega r^2} \quad (30)$$

$$\mu' = \frac{d^2 \bar{\Sigma}}{d \ln r^2} \quad \delta' = \frac{d^2 \bar{T}}{d \ln r^2} \quad (31)$$

To add in the effects of viscosity we first use the alpha parametrization of viscosity and take  $\nu = \alpha \frac{T}{\Omega}$  (?). The

corrections due to shear ( $\alpha_s$ ) and bulk ( $\alpha_b$ ) viscosities are,

$$A_\nu = -\frac{i\alpha_s}{6}\mathcal{H}\left(\frac{65}{2} + \delta - 2\mu + 18\mu'\right) \quad (32)$$

$$B_\nu = -\frac{i\alpha_s}{3}\mathcal{H}\left(-\frac{19}{2} - 7\delta + 2\mu\right) + i\alpha_b\mathcal{H}\left(\frac{5}{2} + \delta + \mu\right) \quad (33)$$

$$C_\nu = -\frac{i2\alpha_s}{3}\mathcal{H} - i\alpha_b\mathcal{H} \quad (34)$$

We solve (??) as a generalized eigenvalue problem by discretizing the eccentricity on a logarithmic grid in radius.

$$\Omega_p \mathbf{Q} \mathbf{e} = \mathbf{M} \mathbf{e} \quad (35)$$

The matrices  $\mathbf{Q}$ , and  $\mathbf{M}$  are the boundary condition matrix and the coefficient matrix, respectively. We solve for the spectrum of normal eigenmodes,  $\mathbf{e}_n$  and their associated (possibly complex) eigenvalues  $\Omega_{p,n}$ .

### 3.3. Boundary Condition

We adopt a zero Lagrangian pressure boundary condition at both the inner and outer boundaries. Using the equations of motion it can be shown that this is equivalent to satisfying

$$r \frac{de(r)}{dr} \Big|_{r_i, r_o} = \tilde{\beta} \left[ \frac{\tilde{\beta} - i\gamma}{\tilde{\beta}^2 + \gamma^2} \right] \frac{d \ln \bar{T}}{d \ln r} e(r) \Big|_{r_i, r_o} \quad (36)$$

at each boundary in the slow mode approximation. In the isothermal ( $\beta \rightarrow \infty$ ) and adiabatic ( $\beta \rightarrow 0$ ) limits the boundary condition reduces to,

$$r \frac{de(r)}{dr} \Big|_{r_i, r_o} = \begin{cases} \frac{d \ln \bar{T}}{d \ln r} e(r) \Big|_{r_i, r_o} & \text{Isothermal} \\ 0 & \text{Adiabatic} \end{cases} \quad (37)$$

## 4. METHODS

## 5. RESULTS

We studied the growth rates of unstable modes in the slow mode ( $\Omega_p \ll \Omega_K$ ) approximation. The classical WKB dispersion relation for a self gravitating and isothermal disk (see e.g. ?) is

$$\kappa^2 - m^2 \varpi^2 - 2\pi G \Sigma |k_r| + c^2 k_r^2 = 0 \quad (38)$$

Where  $\varpi \equiv \Omega - \Omega_p$ . In the  $m = 1$  slow mode limit this simplifies to (?)

$$2\Omega(\Omega_p - \omega_p) = 2\pi G \Sigma |k_r| - c^2 k_r^2 \quad (39)$$

Where  $\omega_p = \Omega - \kappa$  is the orbital precession frequency of a fluid element. From the dispersion relation it is clear that pressure creates retrograde modes ( $\Omega_p < 0$ ) and self gravity tends to create prograde modes ( $\Omega_p > 0$ ). Additionally, global modes (i.e low  $k_r$ ) also tend to create prograde modes (?).

To understand the implications of cooling on the disk, we write the the WKB dispersion relation for a disk which has consonant cooling  $\beta$  and constant background profiles. After some algebra, we obtain

$$\kappa^2 - m^2 \varpi^2 - 2\pi G \Sigma |k_r| + k_r^2 c_{\text{cool}}^2 = 0 \quad (40)$$

$$c_{\text{cool}}^2 = \frac{m\varpi}{m\varpi - i\tilde{\beta}\Omega} c_{\text{adi}}^2 - \frac{i\tilde{\beta}\Omega}{m\varpi - i\tilde{\beta}\Omega} c_{\text{iso}}^2 \quad (41)$$

In the  $m = 1$ , slow mode limit we obtain

$$2\Omega(\Omega_p - \omega_p) = 2\pi G\Sigma |k_r| - k_r^2 c_{\text{cool}}^2 \quad (42)$$

$$c_{\text{cool}}^2 = \frac{1}{1 - i\tilde{\beta}} c_{\text{adi}}^2 + \frac{i\tilde{\beta}}{i\tilde{\beta} - 1} c_{\text{iso}}^2 \quad (43)$$

Where  $c_{\text{adi}}^2 = \gamma c_{\text{iso}}^2$  is the sound speed in the adiabatic ( $\beta = 0$ ) limit. Figure shows the dependence of the decay rate with  $\beta$ .

FIG. 1.—

### 5.1. Lowest Order Mode with No Self Gravity

The mode with zero nodes is perhaps the simplest to understand.

### 5.2. Self Gravity

To include the effects of the disk's self gravity, we include the potential due to the perturbed surface density,

$$\phi' = -G \int dr' r' \Sigma'(r') \int d\phi \frac{\cos \phi}{\sqrt{r^2 + r'^2 - 2rr' \cos \phi}} \quad (44)$$

The  $\phi$  integral is simply the Laplace coefficient,  $b_{1/2}^{(1)}$

$$b_{1/2}^{(1)} \left( \frac{r'}{r} \right) = \frac{2}{\pi r} \int_0^\pi d\phi \frac{\cos \phi}{\sqrt{1 + \left( \frac{r'}{r} \right)^2 - 2 \left( \frac{r'}{r} \right) \cos \phi}} \quad (45)$$

So that the potential is,

$$\phi' = -\frac{G\pi}{r} \int dr' r' \Sigma'(r') b_{1/2}^{(1)} \left( \frac{r'}{r} \right) \quad (46)$$

There is also an "edge" contribution to the potential due to there being a non-negligible excess of material outside the outer boundary of the disk and a deficit of disk material inside the inner boundary of the disk. At the outer boundary of the disk we have,  $\Sigma'(r)dr = \bar{\Sigma}(r_o)\xi_r(r_o) = \bar{\Sigma}(r_o)r_o e(r_o)$ . Similarly at the inner boundary we have,  $\Sigma'(r)dr' = -\bar{\Sigma}(r_i)\xi_r(r_i) = \bar{\Sigma}(r_i)r_i e(r_i)$ . The "edge" potential is thus,

$$\phi_{\text{edge}} = -\frac{G\pi\bar{\Sigma}(r_o)r_o^2 e(r_o)}{r} b_{1/2}^{(1)} \left( \frac{r_o}{r} \right) + \frac{G\pi\bar{\Sigma}(r_i)r_i^2 e(r_i)}{r} b_{1/2}^{(1)} \left( \frac{r_i}{r} \right) \quad (47)$$

The perturbed surface density is related to the eccentricity as  $\phi' = -r \frac{d}{dr} (\bar{\Sigma}e)$ . Plugging this in to (??) and integrating by parts gives,

$$\phi' = -\phi_{\text{edge}} - \frac{G\pi}{r} \int dr' \bar{\Sigma}(r') e(r') \partial_{r'} \left( r'^2 b_{1/2}^{(1)} \left( \frac{r'}{r} \right) \right) \quad (48)$$

The "edge" contribution to the potential thus cancels when we take  $\phi' \rightarrow \phi' + \phi_{\text{edge}}$ . The potential enters the eccentricity equation via the term,

$$-\frac{d}{dr} (r^2 \phi') \quad (49)$$
